ABSTRACT:

CHG DATE=19990617 STATUS=O>A positive electrode material comprising particles (1) including at least one electrochemically active hydroxide and a substantially continuous, uniform encapsulant layer (4) surrounding the particles of positive electrode material. The encapsulant layer is formed from a material which, upon oxidation during processing or charging of the electrode, is convertible to a highly conductive form and upon subsequent discharging of the electrode does not revert to its previous form. Preferably, the electrochemically active hydroxide includes at least nickel hydroxide. The encapsulant layer is preferably formed from at least cobalt hydroxide or cobalt oxyhydroxide and is formed by precipitation from a cobalt salt solution, which can be a cobalt sulfate solution. Electrodes which include the electrochemically active material as well as a precipitation process for forming the material are disclosed.

ABSTRACTED-PUB-NO: DE 19910461A
BASIC-ABSTRACT:

NOVELTY - Nickel hydroxide has an oxidation stable cobalt(II) hydroxide coating treated with weak oxy-acid anions.

DETAILED DESCRIPTION - A novel coated nickel hydroxide has an oxidation stable, pastel green colored cobalt (II) hydroxide coating which exhibits no change after 4 weeks storage in atmospheric air. An INDEPENDENT CLAIM is also included for production of the above coated nickel hydroxide by treating a cobalt hydroxide coated, optionally doped nickel hydroxide with a weak inorganic oxy-acid selected from aluminate, borate, carbonate, manganate, molybdate, niobate, phosphate, silicate, tantalate, vanadate and tungstate, oxalate and their alkali metal salts.

USE - The coated nickel hydroxide is used as electrode material in secondary batteries (claimed), especially as positive active material in rechargeable alkaline batteries.

ADVANTAGE - The coated nickel hydroxide has a high oxidation stability, e.g. less than 0.5% conversion of Co (II) into Co (III) after at least 6 months storage in air. The solubility of the cobalt (II) hydroxide coating in alkaline battery electrolytes is unaffected so it can form a three-dimensional highly conductive network using a minimal quantity of cobalt even without the need for a further conductivity additive.
